Five Useful Data Tool Macros
Ting Sa, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH

ABSTRACT

In this paper, five macros are introduced that can work as helpful tools for some common data tasks. The macro “HelpConsistency” can detect those fields that have same name but different data lengths or data types among the SAS data sets and fix the data length inconsistencies automatically. The macro “SelectVars” can select any variables in batches from a SAS data set, for e.g, the variables have similar naming patterns like the same suffix or the middle parts. The macro “ExportExcelWithFormat” can export formatted SAS data to excel files without losing the formats. The macro “FindFiles” can help users find and access their folders and files very easily. The macro “SearchReplace” can search and replace any string in the SAS programs. The paper includes the SAS codes for all these five macros.

INTRODUCTION

In this paper, five macros are presented that can work as useful tools for some common data tasks. Below are the summarizations for the usage of these five macros.

1. The “HelpConsistency” macro[1]: Common tasks that we need to perform are merging or appending SAS® data sets. During this process, we sometimes get error or warning messages saying that the same fields in different SAS data sets have different lengths or different types. If the problems involve a lot of fields and data sets, we need to spend a lot of time to identify those fields and write extra SAS codes to solve the issues. However, if you use the macro “HelpConsistency” in this paper, it can help you identify the fields that have inconsistent data type or length issues. It also solves the length issues automatically by finding the maximum field length among the current data sets and assigning that length to the field. An html report is generated after running the macro that includes the information about which fields’ lengths have been changed and which fields have inconsistent data type issues.

2. The “SelectVars” macro[2]: Often we need to select a subset of variables from a dataset. SAS® software has provided the “SAS variable list” from which we can select the variables without typing their names individually. However, the “SAS variable list” cannot be used in all SAS procedures, such as the SELECT statement in the SQL procedure. Also, there is no “SAS variable list” available to select variables that share a common suffix or middle part in their names. In this paper, the “SelectVars” macro is introduced that not only incorporates the “SAS variable list” to select a subset of variables, but also can be used to select variables that share common patterns in their names. Additionally, the results from the macro can be applied to all SAS procedures.

3. The “ExportExcelWithFormat” macro[3]: When using SAS to export data to excel, the formats got lost. In this paper, we introduce the macro “ExportExcelWithFormat” that can help you to export formatted SAS data to excel files without losing the formats. The advantage of this macro is that it only requires you to provide the input data set and the location and the name of the output excel file, it will then create the excel file that preserves all the formats in the SAS data set for you.

4. The “FindFiles” macro: The “FindFiles” macro can help users find and access their folders and files very easily. By providing a path to the macro and letting the macro know which folders and files you are looking for under this path, the macro creates an HTML report that lists the matched folders and files. The best part of this HTML report is that it also creates a hyperlink for each folder and file so that when a user clicks the hyperlink, it directly opens the folder or file. Users can also ask the macro to find certain folders or files by providing part of the folder or file name as the search criterion. The results shown in the report can be sorted in different ways so that it can further help users quickly find and access their folders and files.

5. The “SearchReplace” macro: The “SearchReplace” macro can search and replace any string in the SAS programs. To use the macro, the user only needs to pass the folder name, the search string to it. If the user wants to use the replacement function, the user also needs to pass the replacement string to the macro. The macro will check all the SAS programs in this folder and the subfolders to find out which files contain the search string. The macro will generate new SAS files for the replacement so that the old files will not be affected. An html report will be generated by the macro to include the original file locations, the line number of the SAS codes that contain the search string and the SAS codes with search string highlighted in yellow. If you use the replacement string function, the html report will
Five Useful Data Tool Macros, continued

also include the location information for the new SAS files. The location information in the HTML report is created with hyperlinks, so the user can directly open the files from the report.

**THE HELP_CONSISTENCY MACRO**

Presented below are the SAS codes for the Help_Consistency macro:

```sas
%macro Help_Consistency(libnm=,datasets=%str());
%let datasets=%sysfunc(upcase(&datasets.));

proc sql noprint;
*select all the variables from the data sets and save them in data set   tmp1;

%if &datasets.= %then %do;
create table tmp1 as
select libname,name,type,length,memname
from dictionary.columns
where libname=upcase("&libnm.") and memtype="DATA";
%end;

%else %do;
create table tmp1 as
select libname,name,type,length,memname
from dictionary.columns
where libname=upcase("&libnm.") and upcase(memname) in (&datasets.) and
memtype="DATA";
%end;

*select all the variables that have different lengths for the same type;
create table tmp2 as
select * from tmp1 where name in
(select distinct name from
(select name,type,count(distinct length) as length_ct from tmp1
group by name,type having calculated length_ct >1))
and type ^="num" order by name,type,length,memname;

*find the maximum length of a variable and save the result to tmp3;
create table tmp3 as
select t.*,max_length from tmp2 as t,(select name,type,max(length) as
max_length from tmp2 group by name,type) as m
where t.name=m.name and t.type=m.type and t.length ^=m.max_length;
quit;

*prepare the SAS codes to change the length to the maximum length;
data tmp3;
set tmp3;
length codes $500.;
codes=catx(" ","proc sql;alter table",cats(libname,".",memname),
"modify",name,cats("char(",max_length,") format=$",max_length,".;quit;")));
run;

*execute the SAS codes to make the length consistent;
data _null_; 
set tmp3;
call execute(codes);
run;

*save the length change info to the data set tmp4;
data tmp4;
set tmp3;
length comments $200.;
```
Five Useful Data Tool Macros, continued

```sas
comments=catx(" ","the length of data field ",name," in",libname,".",memname," has been changed from ",length," to ",max_length);
keep comments;
run;

proc sql;
*find the variables with different types;
create table tmp5 as
select * from tmp1 where name in
(select distinct name from
(select name,count(distinct type) as type_ct
from tmp1 group by name
having calculated type_ct >1))
order by name,type,memname;
quit;

data tmp5;
set tmp5;
dataset=cats(libname,".",memname);
field_name=name;
field_type=type;
keep dataset--field_type;
run;

proc sort data=tmp5;by field_name dataset field_type;
ods html;
title "Data Fields that have different data types";
proc print data=tmp5;run;
title "Data Fields whose length have been modified";
proc print data=tmp4;run;
ods html close;
ods listing;
proc datasets;delete tmp1-tmp5;run;quit;
%mend;
```

To call the macro, you just need to pass the library name of the input datasets to the macro parameter “libname” and the input SAS datasets’ names to the “datasets” macro parameter. The input data sets must be saved in the same library. For example, by running the following SAS codes, you will get 3 SAS data sets “sample1”, “sample2”, “sample3” which are saved in the working library.

data sample1;a="abc";b=1;run;
data sample2;a="abcde";run;
data sample3;b="one";run;

You can use the following SAS codes to check the data length and data type inconsistencies among the 3 data sets:

```sas
%help_consistency(libnm=work,datasets=%str('sample1','sample2','sample3'));
```

If you want to check all the data sets in a library, you don’t need to pass the values to the “datasets” macro variable. For e.g, if you want to check all the data sets in the “work” library, you just need to call the macro in this way:

```sas
%help_consistency(libnm=work);
```

After running the macro, the macro will create an html report to summarize the field lengths that have been changed and report the data type issues if there are any. See figure1 for a sample html report.
THE SELECTVARS MACRO

Presented below are the SAS codes for the “SelectVars” macro. After calling the macro, the selected variables will be saved into a macro variable “lstVars,” and you can use this macro variable in any SAS procedures to select the variables you want.

```
%macro SelectVars(libname=, datanm=, range=_ALL_, pattern=%, separateby=%str( ));
data tmp; set &libname..&datanm.; run;
%if "&range." ^=%str() %then %do;
data tmp; set tmp; keep &range.; run;
%end;
%global lstVars;
%let lstVars=%str( );
proc sql noprint;
select name into :lstVars separated by "&separateby." from dictionary.columns where libname="WORK" and memname = upcase("tmp") and name like "&pattern."
escape '#';
drop table tmp;
quit;
%mend;
```

- The macro parameter “libname” is used to identify the library name for the dataset from which you want to select the variables.
- The macro parameter “datanm” is used to identify the dataset name from which you want to select the variables.
- The macro parameter “range” is used to identify the range in the dataset from which you want to select the variables. The values that are accepted by the “range” parameter are those that you can use for the “SAS variable list”.

Examples of acceptable “range” parameter values:
1. To select the variables a1, a2, a3, simply pass “a1-a3” to the parameter “range”
2. To select the variables from a1 to b2 based on the variable order in the dataset, simply pass “a1--b2” to the parameter “range”
3. To select the numerical variables from a1 to b2, simply pass a1-numeric-b2 to the parameter “range”
4. To select variables whose name is prefixed with “a,” simply pass “a:” to the parameter “range”
5. Likewise, the keywords “_CHARACTER_”, “_NUMERICAL_”, “_ALL_” could also be passed to the parameter “range”.
By default, the value for the "range" parameter is _ALL_, if you want to define the variable range as all the variables, you don’t need to pass a value to the "range" parameter.

- The macro parameter “patterns” is used to identify the naming patterns of the variables you want to select. In this paper, we use the "like" condition and the wildcard characters "%" and "_" in PROC SQL to help us identify the naming patterns. The wildcard character "_" could be used as a substitute for a single character, and the wildcard character "%" could be used as a substitute for zero or more characters.

The sample code below illustrates how to use the wildcard characters. In this example, we want to select those variables whose names have the suffix "_abc" from the dataset "test" saved in the "work" library.

```sas
proc sql;
select name from dictionary.columns
where libname= upcase("work") and memname = upcase("test") and
name like "%_abc" escape '#';
quit;
```

The "escape" clause is used to search for literal instances of the percent (%) and underscore (_) characters, which are usually used for pattern matching. SAS® allows for variable names beginning with "_", and it happens that "_" is a wildcard character. Thus, to select variables that contain the "_" in their names, we could use an ESCAPE character and add this ESCAPE character before the "_" to tell SAS® the "_" is not a wildcard character. In the above syntax, the "#" is used as the ESCAPE character.

Suppose you want to select those variables whose names start with an "a," followed by a character, then followed by "_123" in the middle, and end with "b." To accomplish this, you could pass "a_#_123%b" to the parameter "pattern."

The default value for the "pattern" parameter is %, which means to select all the patterns. If you want to select all the patterns, you don’t need to pass a value to the "pattern" parameter.

- The macro parameter “separateby” instructs SAS® to separate the selected variables by a space or by a comma. By default, the variables are separated by a space. If you want to separate by comma, you could pass "%str(,)" to the "separateby."

Below are some examples of calling the “SelectVars” macro to get different variables you want, figure2 is a sample SAS data set called “testdata”:

```
<table>
<thead>
<tr>
<th>a1</th>
<th>a2</th>
<th>a3</th>
<th>a1_b1_c1</th>
<th>a2_b2_c2</th>
<th>a3_b3_c3</th>
<th>a4_b4_c4</th>
<th>a5_b5_c5</th>
<th>a6_b6_c6</th>
<th>b1</th>
<th>b2</th>
<th>b3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>1</td>
<td>a</td>
<td>1</td>
<td>a</td>
<td>1</td>
<td>a</td>
<td>1</td>
<td>a</td>
<td>a</td>
<td>3</td>
</tr>
</tbody>
</table>
```

**Figure 2. The “testdata” SAS Data Set**

Example1: Select the variables a1, a2, a3 and separate the variables by comma:

```sas
%selectVars(libname=work, datanm=testdata, range=a1-a3, separateby=%str(,));
%put &lstVars.;
```

The result is: a1, a2, a3

Example2: Select the numerical variables from a1_b1_c1 to a6_b6_c6 and separate the selected variables by space:

```sas
%selectVars(libname=work, datanm=testdata, range=a1_b1_c1-numeric-a6_b6_c6); %put &lstVars.;
```

The result is: a1_b1_c1 a3_b3_c3 a5_b5_c5

Example3: Select the variables whose names have prefix “a” and separate the variables by comma:

```sas
%selectVars(libname=work, datanm=testdata, pattern=a%, separateby=%str(,));
%put &lstVars.;
```
The pattern “a%” means the names’ first character is “a”, the “%” is the wildcard character that substitutes zero or more characters after “a”.

The result is: a1, a2, a3, a1_b1_c1, a2_b2_c2, a3_b3_c3, a4_b4_c4, a5_b5_c5, a6_b6_c6

Example4: Select the variables whose names’ middle parts are “_b”, followed by a character, and followed by “_c”, separate the variables by space:

```
%selectVars(libname=work, datanm=testdata, pattern=%#_b_#_c%);
%put &lstVars.;
```

The result is: a1_b1_c1 a2_b2_c2 a3_b3_c3 a4_b4_c4 a5_b5_c5 a6_b6_c6

Example5: Select the variables whose names end with “_c”, followed by a character, separate the variables by comma:

```
%selectVars(libname=work, datanm=testdata, pattern=%#_c_, separateby=%str(,));
%put &lstVars.;
```

The result is: a1_b1_c1, a2_b2_c2, a3_b3_c3, a4_b4_c4, a5_b5_c5, a6_b6_c6

Example6: Select the character variables from a1 to a6_b6_c6 whose names’ suffix is 2; separate the selected variables by comma:

```
%selectVars(libname=work, datanm=testdata, range=a1-character-a6_b6_c6, pattern=%2, separateby=%str(,));
%put &lstVars.;
```

The result is: a2, a2_b2_c2

Below is an example about how to use the macro variable lstVars in the SELECT statement in the SQL procedure, make sure you have used the comma to separate the variables saved in the lstVars:

```
proc sql;
select &lstVars. from testdata;
quit;
```

**THE EXPORTEXCELWITHFORMAT MACRO**

Presented below are the SAS codes for the exportExcelWithFormat macro.

```
%macro ExportExcelWithFormat(libname=, dataname=, outputname=, sheetname=);
proc sql noprint;
create table tmp_vars as select name, format
from dictionary.columns where libname=upcase('&libname.') and
memname=upcase('&dataname.');
quit;
data tmp_vars;
set tmp_vars end=last;
length formatcode $400.;
if format ^="" then formatcode=catx(" ", cats("put","(" ,name,"",",format,")" ),
"as",name,"",")");
else formatcode=cats(name,"","" );
if last then formatcode=substr(formatcode,1,length(formatcode)-1);
run;
%let formatcodes=;
data_null ;
set tmp_vars;
call symput('formatcodes', trim(resolve('&formatcodes.')||' '||trim (formatcode)));
run;
proc sql;
create view tmp_view as select &formatcodes. from &libname..&dataname.;
```

6
Five Useful Data Tool Macros, continued

quit;
%let formatcodes=%str();
PROC EXPORT DATA= tmp_view OUTFILE= "&outputname." DBMS=EXCEL REPLACE;
  SHEET="&sheetname.";
RUN;
proc sql;
drop table tmp_vars;
drop view tmp_view;
quit;
%mend;

* The "libname" is used to indicate the library name for the input dataset.
* The "dataname" is used to indicate the input SAS dataset name.
* The "outputname" is used to indicate the location and the name of the output excel file.
* The "sheetname" is used to indicate the sheet name that contains the outputs in the excel file.

Suppose you have a SAS data set "test" saved in the working library, below are the SAS codes to generate this "test" data set.

proc format;
  value genderfmt 0="Male" 1="Female";
  value racefmt 1="White" 2="black" 0="Other";
  value $YNfmt "Y"="Yes" "N"="No";
run;
data test;
do id=1 to 6;
  gender=mod(id,2);
  race=mod(id,3);
  if gender=0 then yn="Y";else yn="N";
  birthdate="01Jan2015"d+id;
  birthtime="00:00:00"t+id;
  format gender genderfmt. race racefmt. yn $YNfmt. birthdate yymmdd10. birthtime time8.;
  output;
end;
run;

Figure 3. A Sample Input Data Set “test” Saved in the “work” Libarary

<table>
<thead>
<tr>
<th>id</th>
<th>gender</th>
<th>race</th>
<th>yn</th>
<th>birthdate</th>
<th>birthtime</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Female</td>
<td>White</td>
<td>No</td>
<td>2015-01-02</td>
<td>00:00:01</td>
</tr>
<tr>
<td>2</td>
<td>Male</td>
<td>black</td>
<td>Yes</td>
<td>2015-01-03</td>
<td>00:00:02</td>
</tr>
<tr>
<td>3</td>
<td>Female</td>
<td>Other</td>
<td>No</td>
<td>2015-01-04</td>
<td>00:00:03</td>
</tr>
<tr>
<td>4</td>
<td>Male</td>
<td>White</td>
<td>Yes</td>
<td>2015-01-05</td>
<td>00:00:04</td>
</tr>
<tr>
<td>5</td>
<td>Female</td>
<td>black</td>
<td>No</td>
<td>2015-01-06</td>
<td>00:00:05</td>
</tr>
<tr>
<td>6</td>
<td>Male</td>
<td>Other</td>
<td>Yes</td>
<td>2015-01-07</td>
<td>00:00:06</td>
</tr>
</tbody>
</table>

Figure 4. Formats in the “test” SAS Data Set
You can call the macro like this:

```sql
%exportExcelWithFormat(libname=work, dataname=test, outputname=%str(C:\test.xlsx),
                    sheetname=sheet1);
```

This will create an excel file “test.xlsx” that is saved on the C: drive and the sheet name that contains the result is called “sheet1”.

![Figure 5. The “test.xlsx” File with the Formats](image)

**THE FINDFILES MACRO**

Below are the macro codes:

```sql
%macro FindFiles(dirnm=, outhtml=, filetype=%str(), sortvars=%str(),
                 browser_type=iexplore);
filename DIRLIST pipe "dir /- /q /s /t:w "&dirnm" ";

data tmp1;
length path filename $255 line $1024 owner $17 temp $16;
retain path;
infile DIRLIST length=reclen;
input line $varying1024.; reclen;
if reclen = 0 then delete;
if scan(line,1," ")='Volume' or scan(line,1," ")='Total' or
scan(line,2," ")='File(s)' or scan(line,2," ")='Dir(s)' then delete;
dir_rec=upcase(scan(line,1," "))='DIRECTORY';
if dir_rec then path=left(substr(line,length("Directory of")+2));
else do;
date=input(scan(line,1," "),mmddyy10.);
time=input(scan(line,2," "),time5.);
post_meridian=(scan(line,3," ")='PM');
if post_meridian then time=time+'12:00:00'T;
temp = scan(line,4," ");
if temp='<DIR>' then size=0; else size=input(temp,best.);
owner=scan(line,5," ");
filename=scan(line,6," ");
if filename in ('.' '..') then delete;
ndx=index(line,scan(filename,1," "));
filename=substr(line,ndx);
end;
run;

data tmp2;
set tmp1;
length Type $20.;
if index(filename,".")=0 then Type="Folder";
else Type=propcase(scan(filename,2,"."));
if filename ^="" then src=cats(path,"\",filename);
else src=path;
```

---

Five Useful Data Tool Macros, continued

THE FINDFILES MACRO

Below are the macro codes:

```sql
%macro FindFiles(dirnm=, outhtml=, filetype=%str(), sortvars=%str(),
                 browser_type=iexplore);
filename DIRLIST pipe "dir /- /q /s /t:w "&dirnm" ";

data tmp1;
length path filename $255 line $1024 owner $17 temp $16;
retain path;
infile DIRLIST length=reclen;
input line $varying1024.; reclen;
if reclen = 0 then delete;
if scan(line,1," ")='Volume' or scan(line,1," ")='Total' or
scan(line,2," ")='File(s)' or scan(line,2," ")='Dir(s)' then delete;
dir_rec=upcase(scan(line,1," "))='DIRECTORY';
if dir_rec then path=left(substr(line,length("Directory of")+2));
else do;
date=input(scan(line,1," "),mmddyy10.);
time=input(scan(line,2," "),time5.);
post_meridian=(scan(line,3," ")='PM');
if post_meridian then time=time+'12:00:00'T;
temp = scan(line,4," ");
if temp='<DIR>' then size=0; else size=input(temp,best.);
owner=scan(line,5," ");
filename=scan(line,6," ");
if filename in ('.' '..') then delete;
ndx=index(line,scan(filename,1," "));
filename=substr(line,ndx);
end;
run;

data tmp2;
set tmp1;
length Type $20.;
if index(filename,".")=0 then Type="Folder";
else Type=propcase(scan(filename,2,"."));
if filename ^="" then src=cats(path,"\",filename);
else src=path;
```
location=cats("<a href='",src,"'>",src,"</a><br>");
date_modified=catx(" ",put(date,yyymmd10.),put(time,5.));
%if %&filetype NE %str() %then %do;
if index(upcase(filename),upcase("&filetype."))>0 or
index(upcase(type),upcase("&filetype."))>0;
%end;
keep Type location date_modified;
label location="Location" date_modified="Date Modified";
run;

data tmp2;
set tmp2;
if index(lowcase(location),"service")>0 then delete;
run;
proc sort data=tmp2 nodupkey;by Location;run;
%if %&sortvars NE %str() %then %do;
proc sort data=tmp2;by &sortvars.;run;
%end;
ods html file="&outhtml.";
proc print data=tmp2 noobs label;run;
ods html close;

options NOXWAIT NOXSYNC;
%if &browser_type.=iexplore %then %do;
x "start iexplore &outhtml.";
%end;
%else %if &browser_type.=chrome %then %do;
%let newhtml=%sysfunc(tranwrd(&outhtml,\\,\\));
x "start &browser_type. file://&newhtml.";
%end;
%mend;

- The "dirnm" is used to indicate the directory you want the macro to search for files and folders.
- The "outhtml" is used to indicate the location and the filename for the output html report.
- The "filetype" is used to indicate the type of the files you want to find, you can pass any values that are available for the column "Type" on the output html report. For e.g, if you want to find the folders, you can pass “folder” to the "filetype" parameter. The parameter "filetype" value is case-insensitive. By default, if you don’t pass any value to it, it will list all the folders and files.
- The "Sortvars" is used to indicate how you want to sort your results. To sort the results by column "Type", pass "type" value to the macro variable "Sortvars". To sort the results by column "Location", pass “location” value to the macro variable "Sortvars". To sort the results by column "Date Modified", pass “date_modified” value to the macro variable "Sortvars". For example, if you want to sort the results by type and descending modified date, you can pass "type descending modified_date" to the "sortvars" macro parameter. By default, if you don’t pass any value to it, it will sort the results by location.
- The "browser_type" is used to indicate which browser you want to use to open your html report. By default, it will use the internet explorer to open the report. You can also pass "chrome" to it to open the file in Google Chrome.

Below are some examples showing you how to call the macro to find different files and sort the results.

1. To Find all the files and folders inside the "C:\generate_html" folder and sort the results by type and descending modified date. The result will be saved into the "result.html" file on the C: drive. and Google Chrome will be used to open the report. You can call the macro in this way:

   %Findfiles(dirnm=%str(C:\generate_html),sortvars=%str(type descending date_modified),outhtml=%str(C:\result.html),browser_type=chrome);
2. To find all the html files inside the “C:\generate_html” folder and sort the results by location and type. The result will be saved into the “C:\result.html” file and the file will be opened by internet explorer by default. You can call the macro in this way:

```%Findfiles(dirnm=%str(C:\generate_html),filetype=%str(.html),sortvars=%str(location type),outhtml=%str(C:\result.html));```

3. To find the “test.pdf” file inside the “C:\generate_html” folder, you can call the macro in this way:

```%Findfiles(dirnm=%str(C:\generate_html),filetype=%str(test.pdf),outhtml=%str(C:\result.html));```

4. To find the folders inside the “C:\generate_html” folder, you can call the macro in this way:

```%Findfiles(dirnm=%str(C:\generate_html),filetype=%str(folder),outhtml=%str(C:\result.html));```

Below are the screenshots for a sample html report. Figure 6 lists all the files and folders under directory “C:\generate_html”. The report in figure 6 is sorted by “Location” column.

![Figure 6. The screenshot for a sample HTML file report](image-url)
If you only want to select all the folders or select all the “jpg” files inside the folder “C:\generate_html” or find a file whose name is “test.pdf”, the macro can help you do those things as well. See the screenshots in Figure 7, 8 and 9.

%end;
%end;
proc datasets lib=work kill;run;quit;
%MEND;

- The "foldernm" is used to indicate the name of the search folder.
- The "searchstring" is used to save the search string.
- The "replacestring" is used to save the replacement string. If you don't want to use the replacement function, you don't need to pass the value to this macro variable.
- The "htmldir" is used to indicate where you want to save the html report. If you don't pass a value to this macro variable, by default, the html report will be saved as "c:\result.html".

The following macro call will search the "%macro" in all the SAS programs located in the "C:\Program Files\SASHome\x86\SASFoundation\9.4\or\sample" folder and its subfolders. If the macro finds any SAS files that contain the search string, the macro will replace the search string with the replacement string "this is a macro;%macro". Then the macro will create new SAS files. The new SAS files are named as "n_" followed by the original file names, for e.g, if the original file name is "test. sas", the new file name will be "n_test.sas". The new files will be saved in the same folder as the original files. The html report will be saved as the "c:\result1.html".

%SearchReplace(foldernm=%str(C:\Program Files\SASHome\x86\SASFoundation\9.4\or\sample),searchstring=%str('%macro'),replacestring=%str('"this is a macro;%macro"'), htmldir=%str(c:\result1.html));
Five Useful Data Tool Macros, continued

If you just want to use the search function, you don’t need to pass a value to the “replacestring” macro variable, the following SAS codes show you an example, by calling the macro in this way, it will search the string “%macro” in the “C:\test” folder and its subfolders, the html report will be saved as “c:\result.html” by default:

%SearchReplace(foldernm=%str(C:\test), searchstring=%str('%macro'));

Figure 11 shows you a sample html report generated by the macro, the search string in this example is “%macro” and the search folders are “C:\Program Files\SASHome\x86\SASFoundation\9.4\or\sample” and its subfolders.

**Figure 11. The Screenshot of a Sample HTML Report for the Search Function**

If we pass the replacement string to the macro, the macro will create new files for those files that contain the search string, replace the search string with the replacement string in those new files. The new files’ names will have the prefix “n_” followed by the original file names. The new files will be saved in the same folder as the original files. Figure 12 shows you a sample html report for the replacement function. The search string is “%macro”, the replacement string is “‘This is a macro: %macro” and the search folders are “C:\Program Files\SASHome\x86\SASFoundation\9.4\or\sample” and its subfolders.
## CONCLUSION

The five macros presented in this paper can be used as helpful tools for some common data tasks. All of the macros have their own published online paper. You can check the reference section to find each individual paper.
